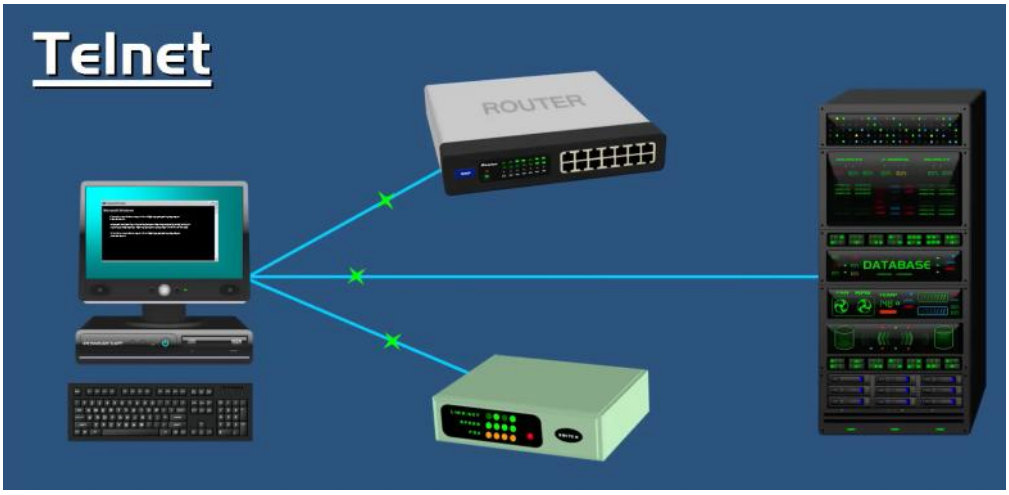
Telnet Vs SSH

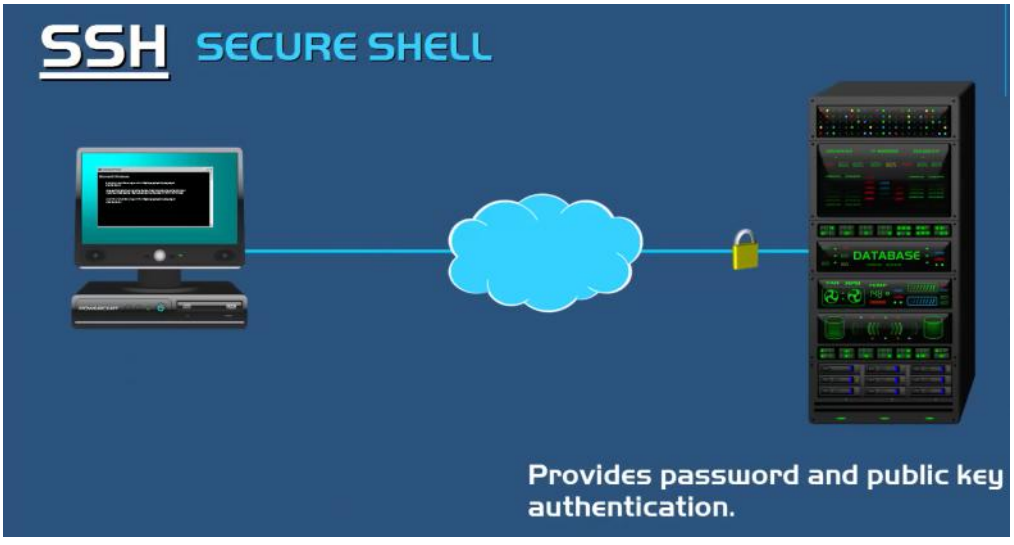
Saturday, April 25, 2026 7:36 PM

Telnet

Telnet stands for Teletype Network developed in 1969 also all the commands are sent in plain text so there is no encryption because of this it is outdated and is replaced by SSH. Telnet is a command line tool used to remotely access and control servers or network devices. It allows you to run commands like creating files, managing services, and browsing directories from another system. Also there is no GUI and all the commands are sent by the keyboard and because of this it is very fast.



- It is fast and simple but sends all data in plain text without encryption, making it insecure for use over the internet.
- Because of this, Telnet is mostly outdated and replaced by SSH, which provides secure encrypted communication and authentication.
- Today, Telnet is mainly used in local networks, testing ports, or with older devices that do not support modern secure protocols.

SSH


SSH or secure shell encrypts the data and protects it from any hackers. It also provides password and public key authentication making it more safer than telnet.
