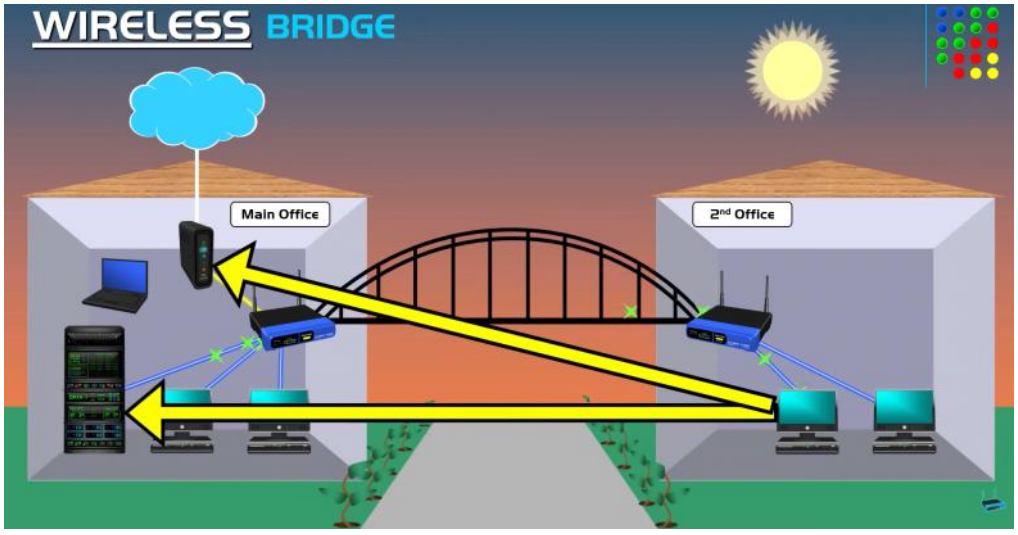
Wireless Bridge Mode

Tuesday, March 24, 2026 7:02 PM

Wireless bridge mode connects two separate networks together wirelessly, forming one local area network (LAN). This setup allows devices in both locations to share resources, such as files on a server and access a single internet connection.

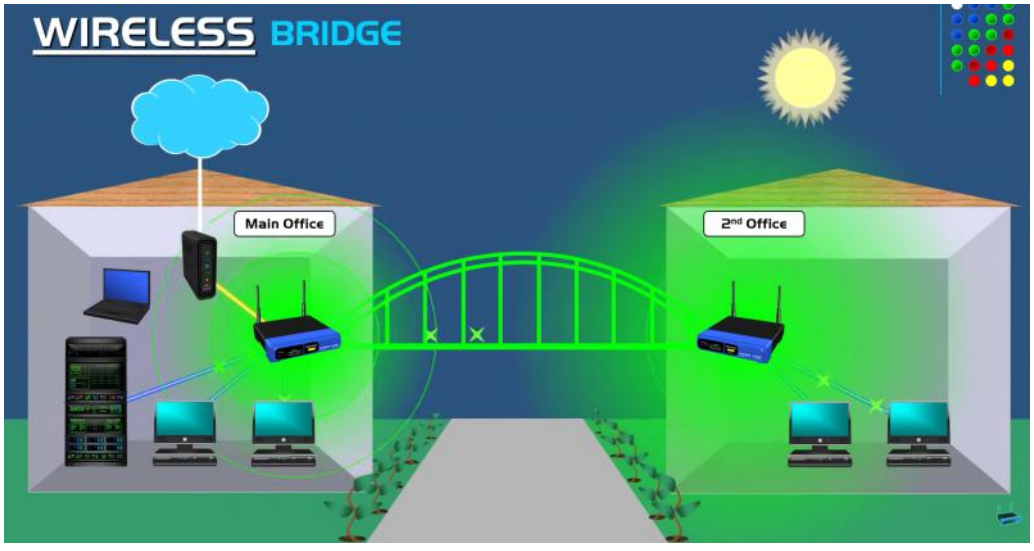


For any reason if this can't be connected with the help of wires, then it is called wireless bridge to make a single LAN network

There is a special type of routers called SOHO routers where it is made up of a combination of switch and router especially made for small offices and small homes to connect each

other to form a LAN

To set this up, a secondary router is configured to act as a bridge, linking to the main router's wireless signal. While the main router manages the entire network, the bridge router has its own routing functions like firewall and DHCP disabled. Depending on the router model, the bridge can provide network access via ethernet cables to wired devices, or broadcast a new wireless signal for Wi-Fi devices.

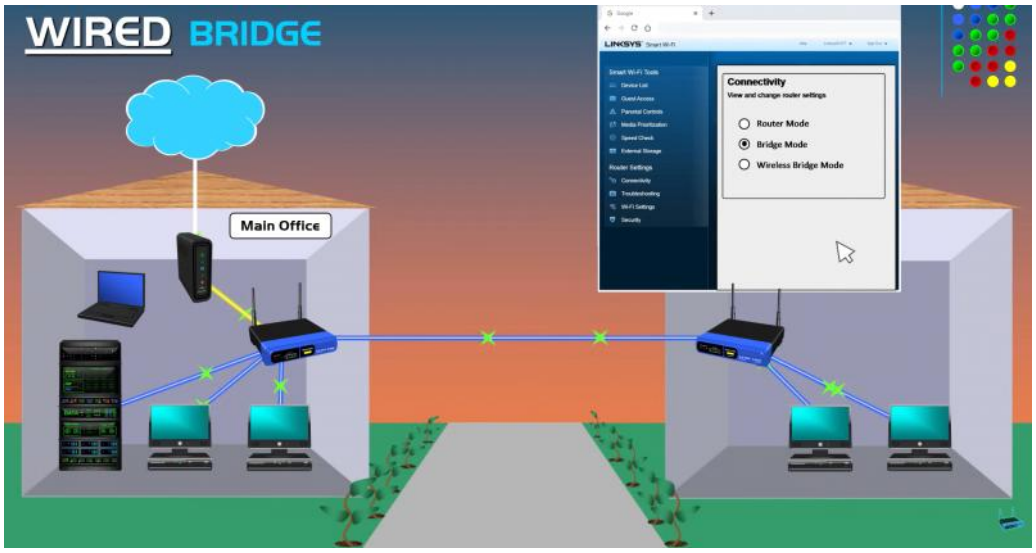


We don't have to do anything in the main router but we have to do some configurations in the 2nd office router

Then this become a single LAN network

By don't this then the 2nd office router is not the gateway for this LAN as well as it does not assigns the IP(DHCP) to the PCs in office 2 as well as the firewall and NAT is managed by the router in the 1st office instead of the 2nd office router

Also we can change the 2nd office router based on our preference if this needs wireless connection enable in the 2nd office or not. It is based on the hardware of the router



The bridge mode is for connecting the routers on wires instead of wireless which is mentioned above
