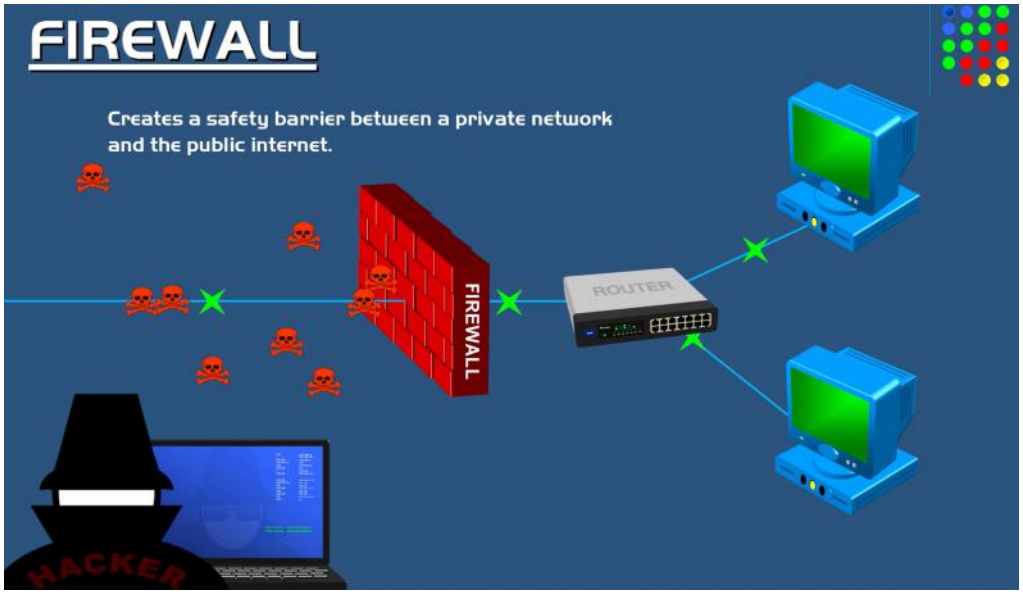
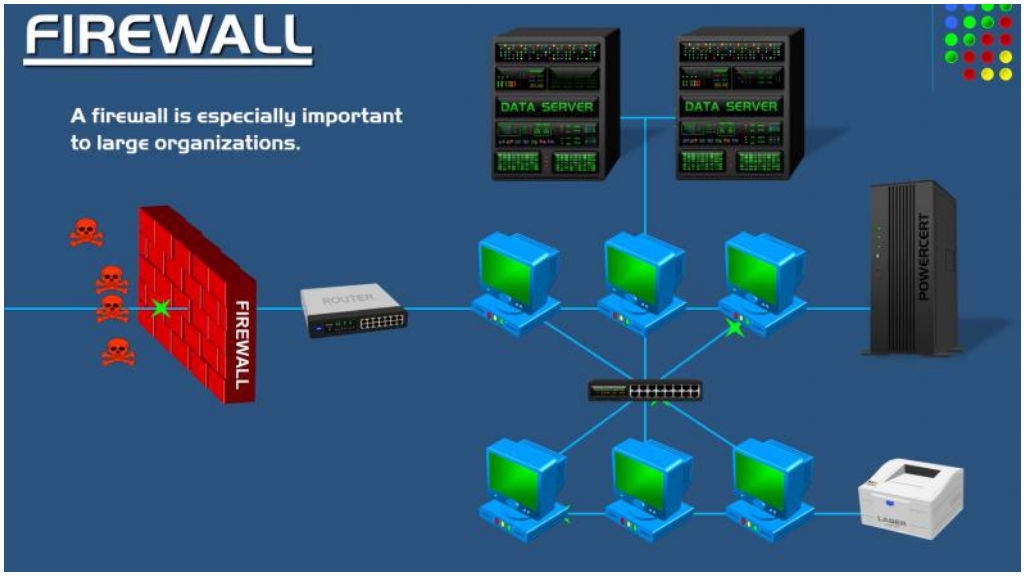
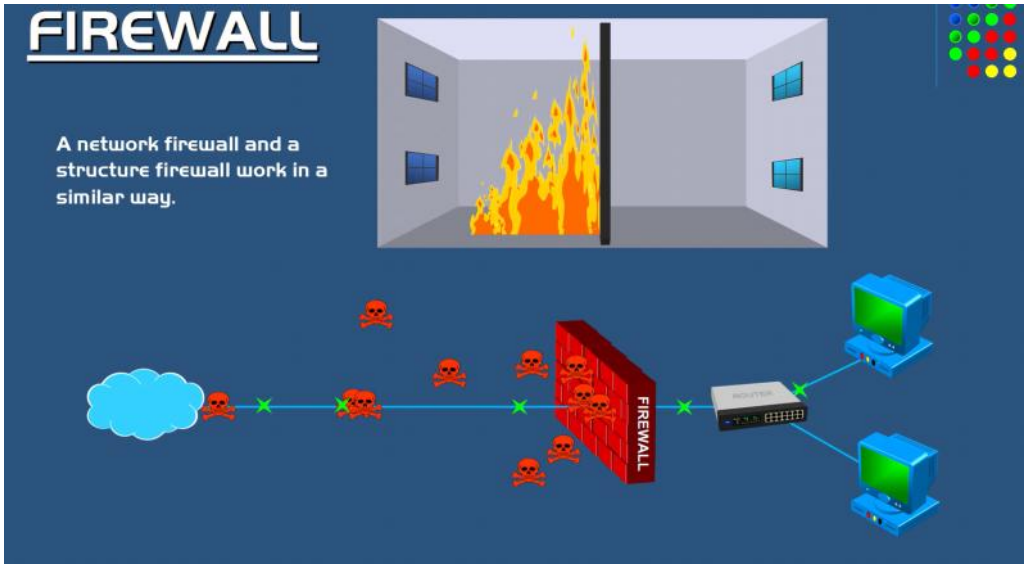
Firewall

Tuesday, March 17, 2026 8:27 PM

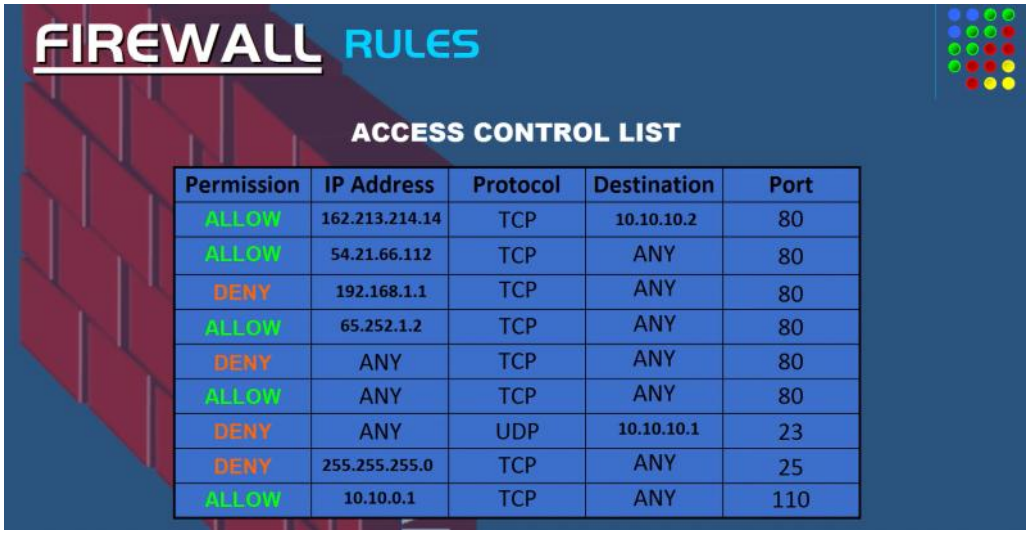
A firewall is a security system that protects a private network by filtering incoming and outgoing traffic. It blocks unauthorized or harmful access while allowing safe communication.



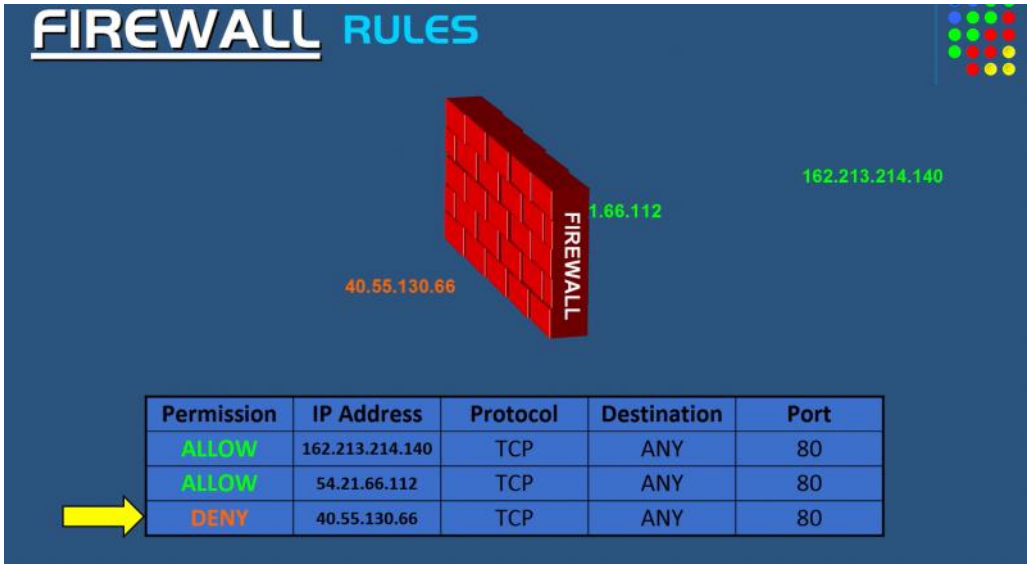




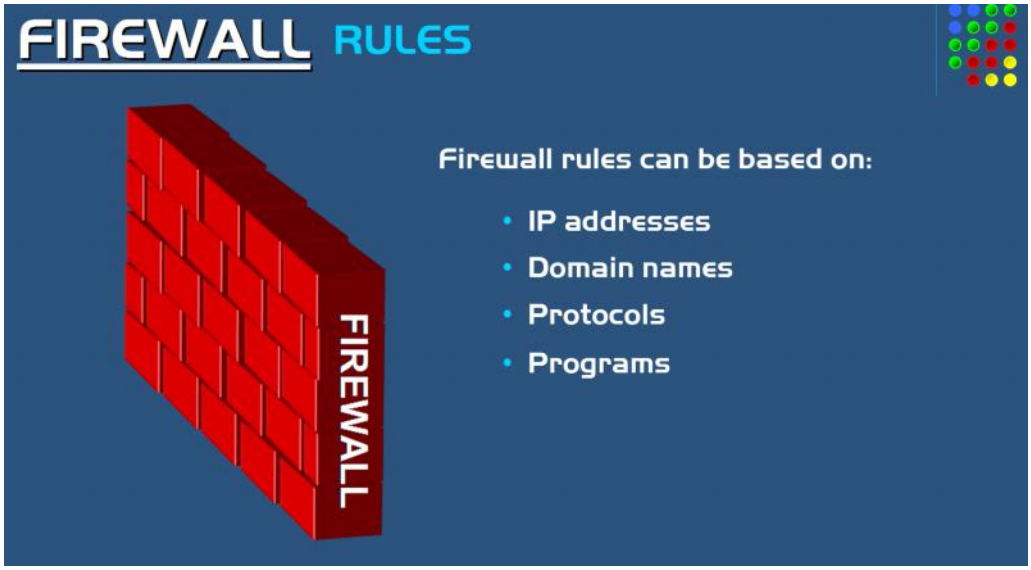
It works using rules called Access Control Lists (ACLs), which decide traffic based on factors like IP address, ports, protocols, and applications.



Permission	IP Address	Protocol	Destination	Port
ALLOW	162.213.214.14	TCP	10.10.10.2	80
ALLOW	54.21.66.112	TCP	ANY	80
DENY	192.168.1.1	TCP	ANY	80
ALLOW	65.252.1.2	TCP	ANY	80
DENY	ANY	TCP	ANY	80
ALLOW	ANY	TCP	ANY	80
DENY	ANY	UDP	10.10.10.1	23
DENY	255.255.255.0	TCP	ANY	25
ALLOW	10.10.0.1	TCP	ANY	110

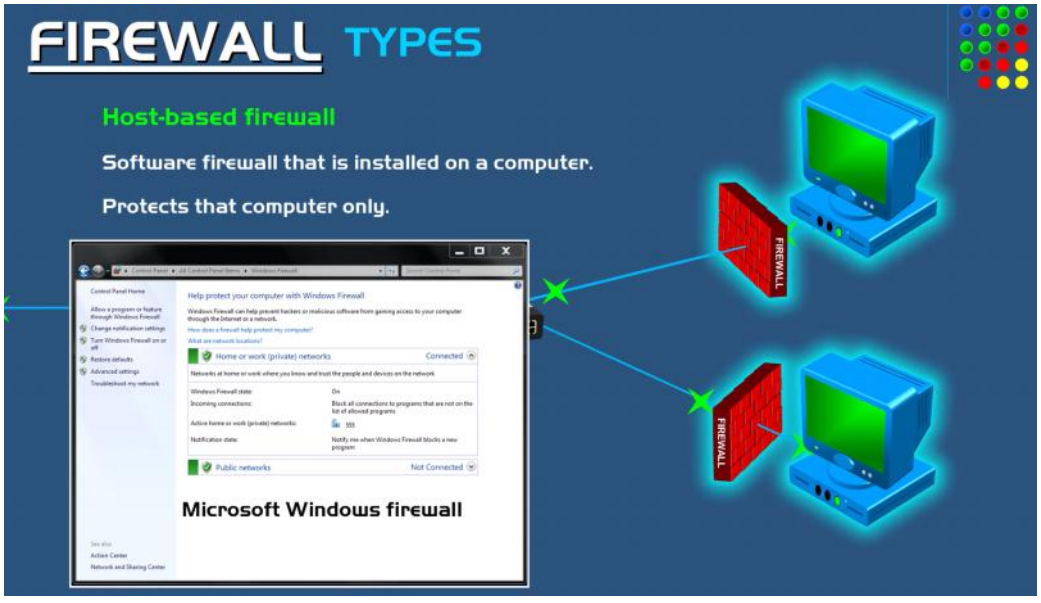


Permission	IP Address	Protocol	Destination	Port
ALLOW	162.213.214.140	TCP	ANY	80
ALLOW	54.21.66.112	TCP	ANY	80
DENY	40.55.130.66	TCP	ANY	80

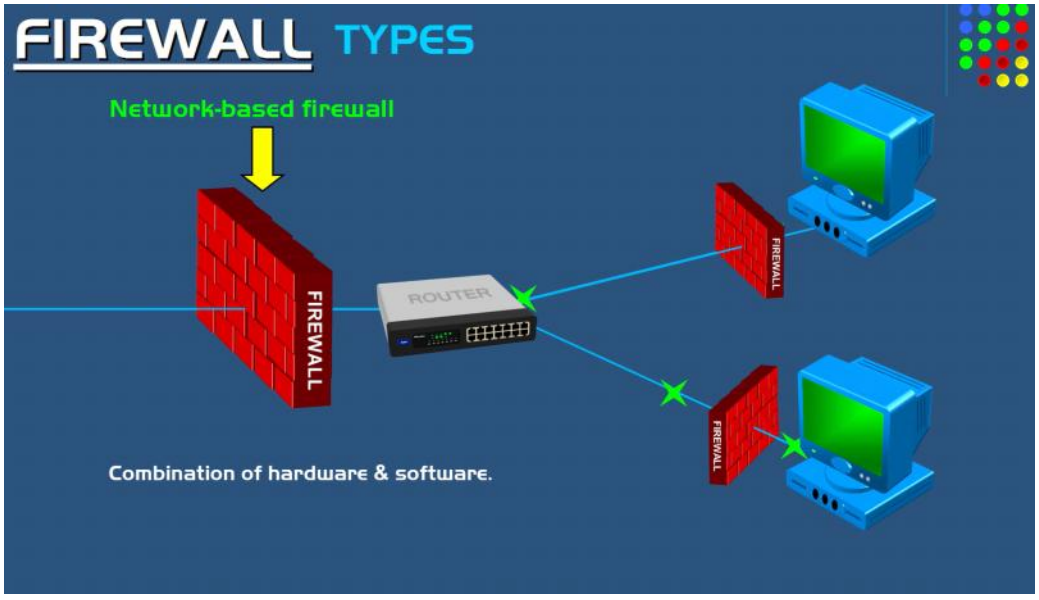


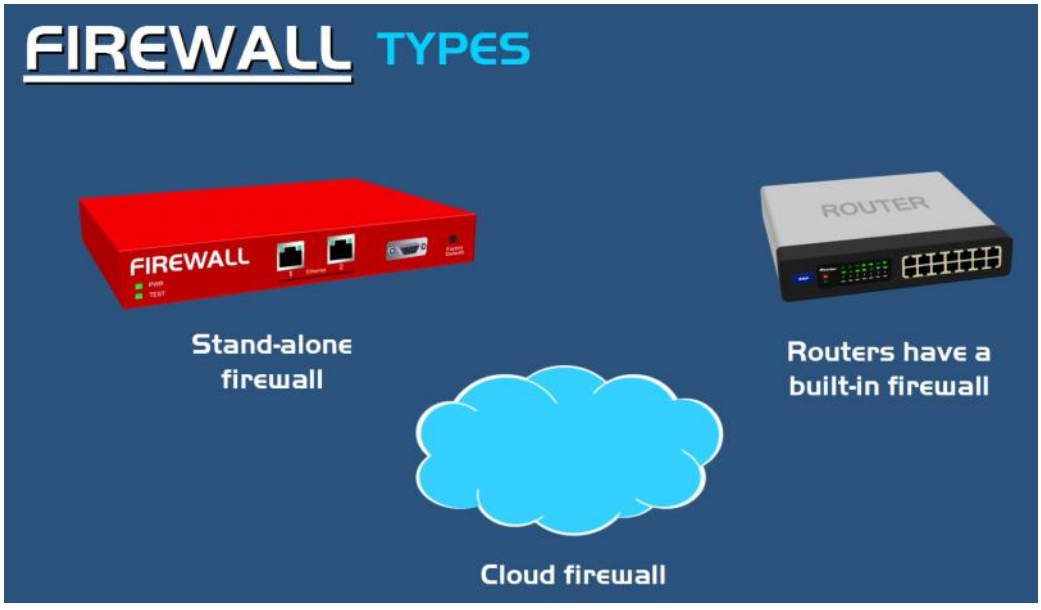
There are two main types:

Host-based firewall which protects a single device

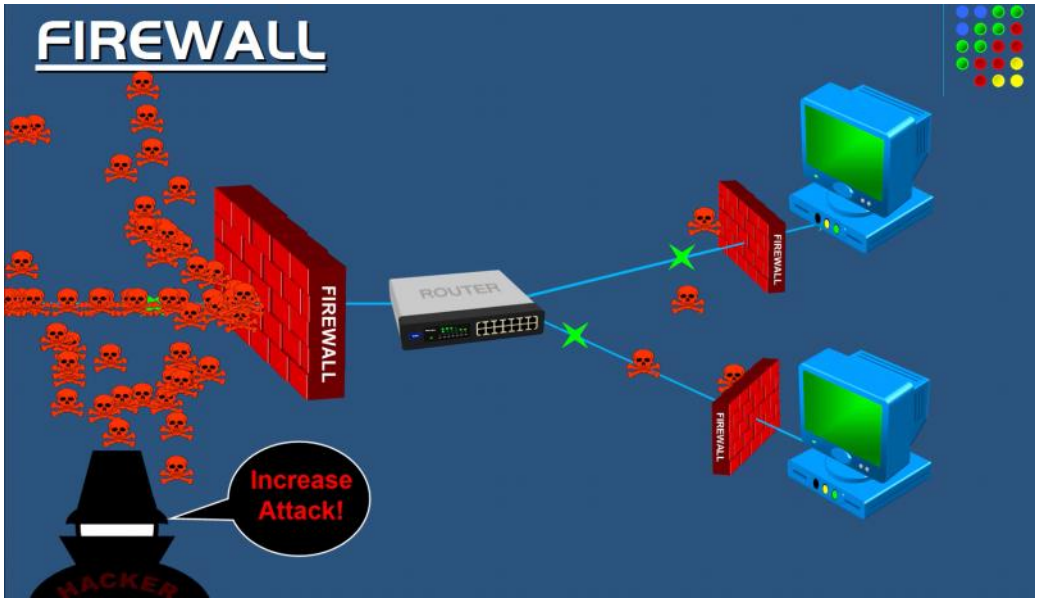


Network-based firewall which protects the entire network





Using both together provides better security by creating multiple layers of protection.



Overall, a firewall acts as a barrier between a private network and the internet, helping prevent attacks and keep data safe.
