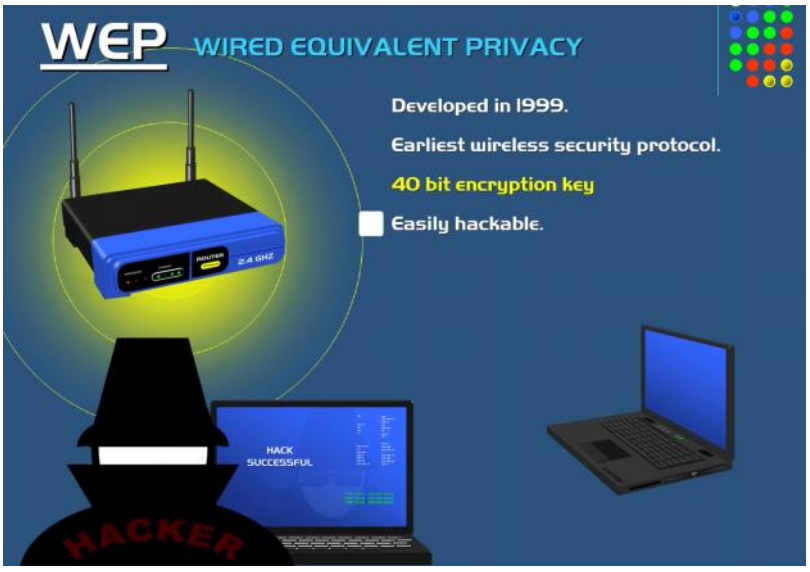
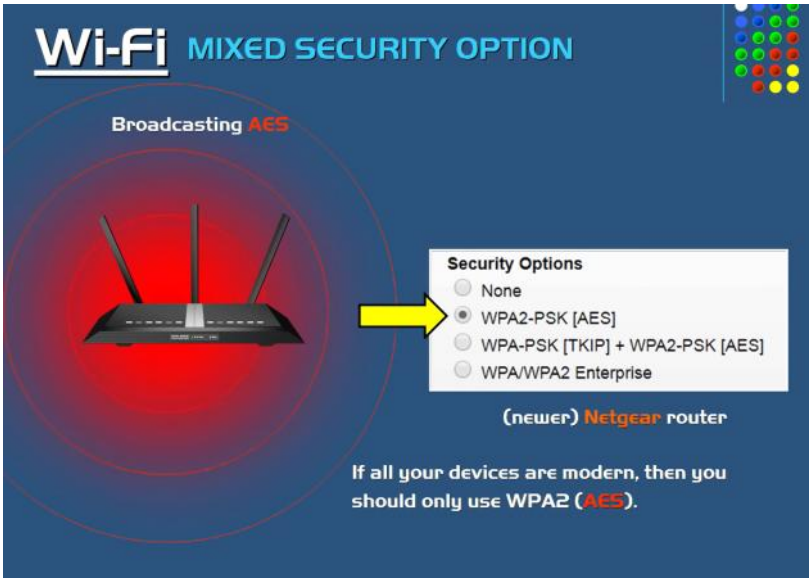
Wi-Fi (Wireless) Password Security

Monday, March 30, 2026 7:50 AM

Wireless networks use various security methods to protect data. WEP (Wired Equivalent Privacy) is the oldest, insecure protocol and should no longer be used. WPA (Wi-Fi Protected Access) improved upon WEP by introducing TKIP (Temporal Key Integrity Protocol), but it is now outdated. WPA2 is currently the standard for strong security, utilizing AES (Advanced Encryption Standard) to resist brute force attacks. WPA3 is the newest protocol, offering cutting-edge security and better protection against password guessing.

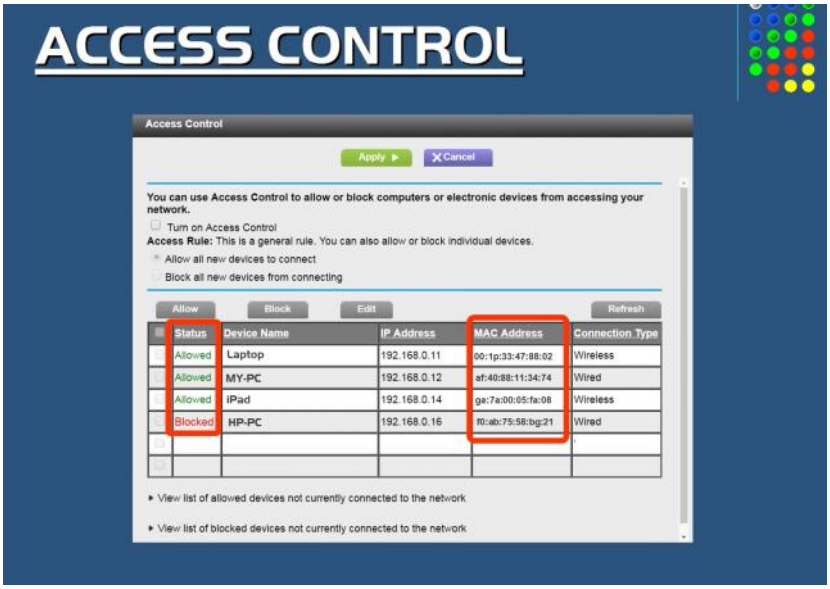




WPA + WPA2 is a mixed option used in router for compatibility issue while older devices will connect to WPA and newer devices will connect to WPA2 but it also makes the network more prone to breach or cyber-attacks so using the WPA 2 is more good if you have newer devices - like devices made after 2006 which supports AES.

PIN Number is the second option used to connect two devices

For easy setup, WPS (Wi-Fi Protected Setup) allows devices to connect without entering a password, typically using a push-button method.



Additionally, Access Control (MAC filtering) provides an extra layer of security by allowing or blocking specific devices based on their unique MAC address.
