

Servers

Saturday, May 2, 2026 3:08 PM

A server is a computer that provides services to other computers clients over a network. It acts as a central system where users can access things like websites files email or databases.

A server is not just a powerful machine it is a role any computer can perform but dedicated servers are built for reliability performance and continuous operation. They use specialized hardware like multi core processors ECC memory RAID storage and backup power to handle heavy workloads and stay online 24 7.

Servers

PROTECTS AGAINST MEMORY ERRORS

Xeon processors support **ECC RAM**.
(Error-Correcting Code)

ECC RAM is mainly used in servers.

Detects if the data was correctly processed.

Desktop CPUs

Intel Core CPUs do **NOT** support ECC RAM ❌

AMD CPUs do support ECC RAM ✅

Servers

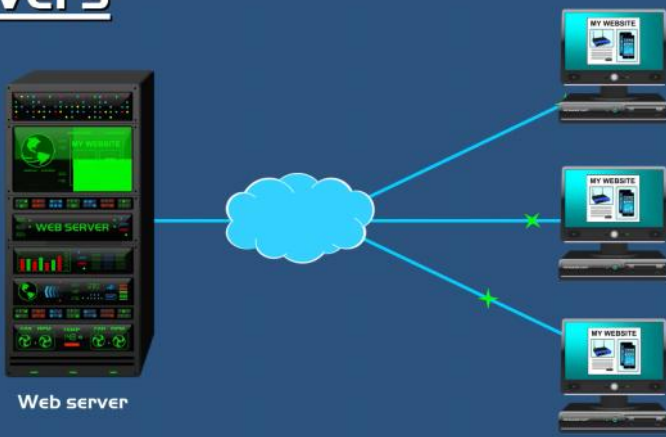

Servers need to use a server operating system.

Server operating systems are robust and stable.

Are able to handle thousands of concurrent connections.

Servers can be set up to handle one specific service or multiple services depending on the organization's needs. Common types include web servers email servers and database servers.
