

Network Ports

Friday, May 1, 2026 11:36 PM

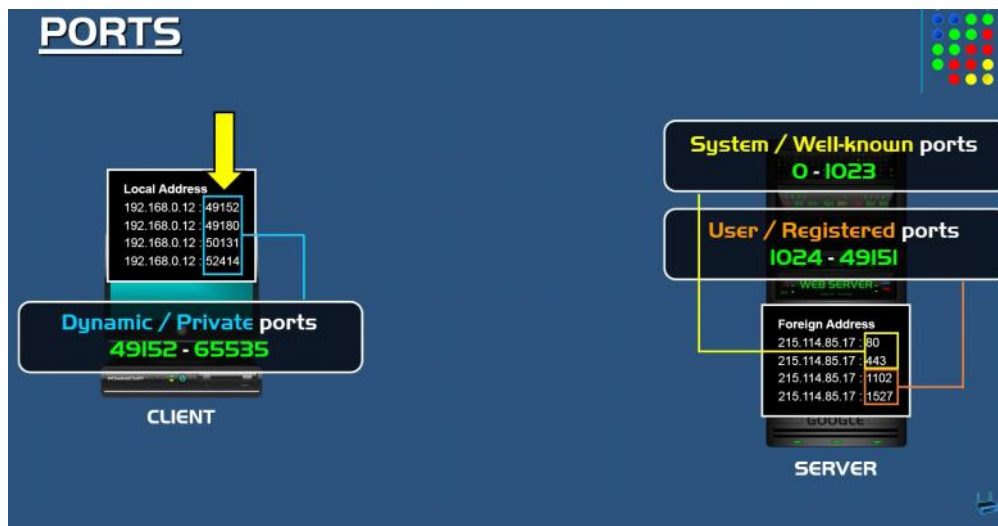

A port is a logical number used to identify a specific service or program on a computer or server. It works together with an IP address, where the IP address finds the device and the port tells which service to use like web, FTP, or email.

Ports range from 0 to 65535. Common ones include 80 for HTTP, 443 for HTTPS, 21 for FTP, and 25 for email.

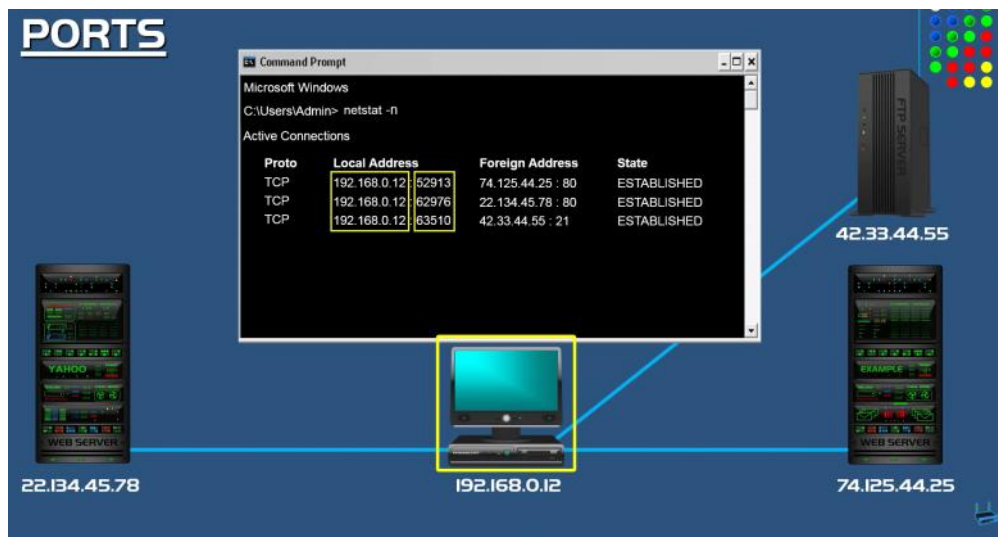

When you access a website, your computer converts the domain into an IP address and adds a port number to request the correct service. The server then uses that port to send the right response.

Ports are divided into three types -

- System or Well-known ports from 0 to 1023 used by common services
- User or registered ports from 1024 to 49151 used by applications
- Dynamic or private ports from 49152 to 65535 used temporarily by client devices

Tools like netstat can show active connections and port usage on a system
