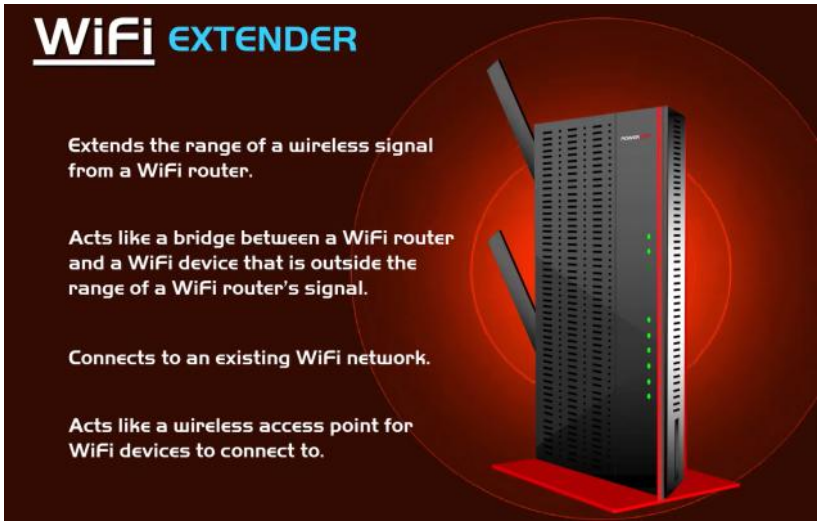
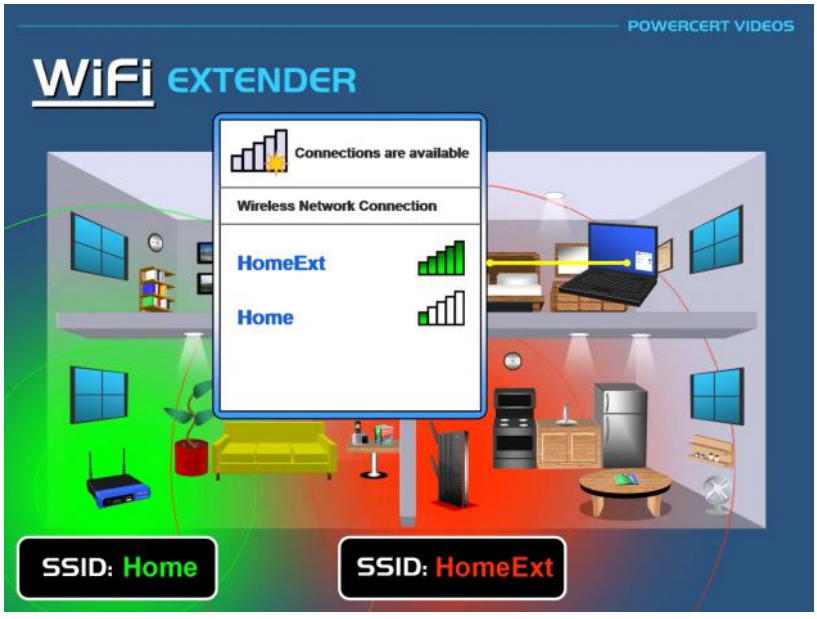
Wi-Fi Range Extender

Wednesday, March 25, 2026 11:03 PM

A Wi-Fi extender (also called a booster) acts as a bridge between a wireless router and devices outside its range. It works by connecting to the main router's signal and broadcasting its own wireless access point to cover areas like distant bedrooms or kitchens.





Key limitations include:

Building structure (walls/floors) weakens the signal.
The extender does not strengthen the original signal; it just broadcasts a new one with internet access provided by the router.
It is best placed in the middle of the home between the router and the dead zone.
