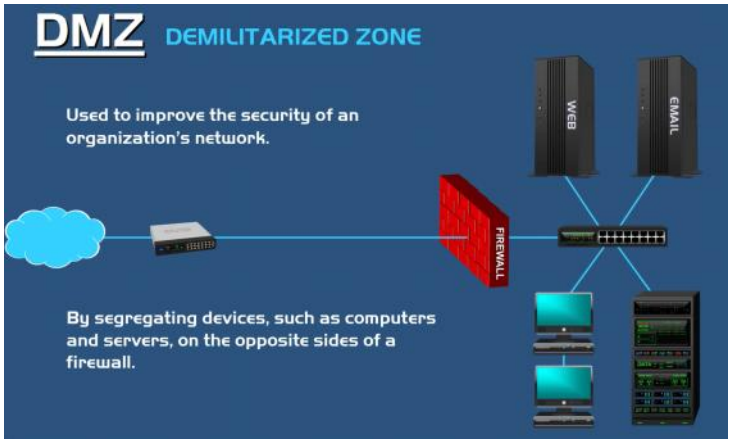
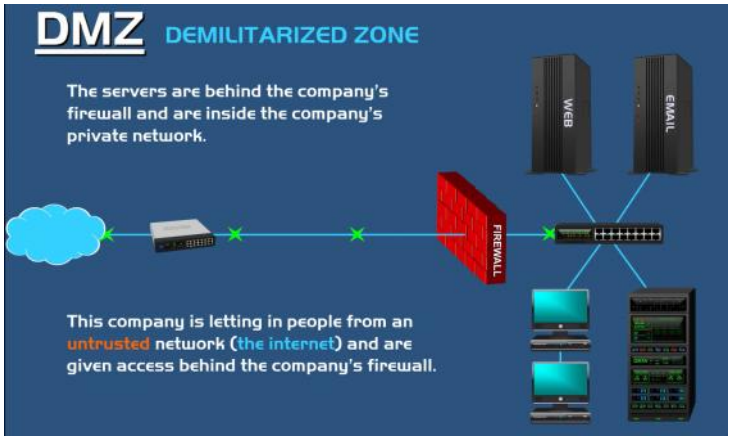
DMZ Demilitarized Zone

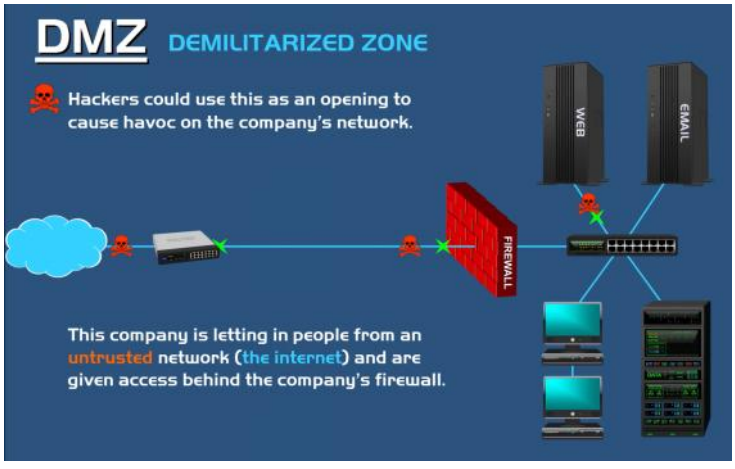


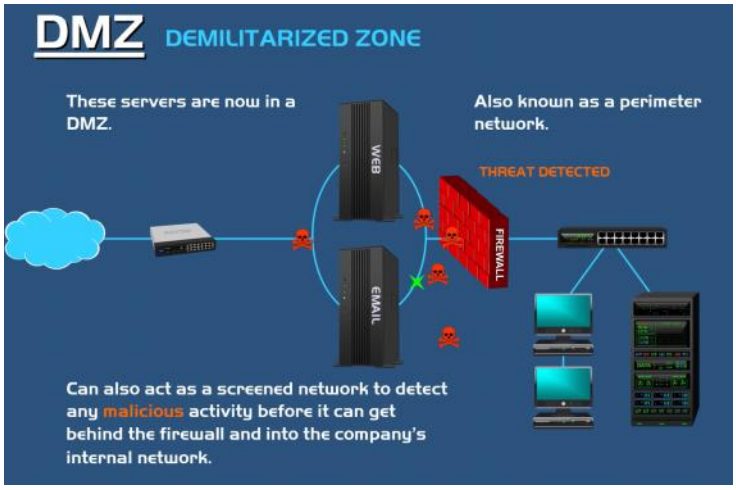
DMZ is a separate network placed between the Internet and an organization's internal network. It acts as a buffer zone to improve network security.

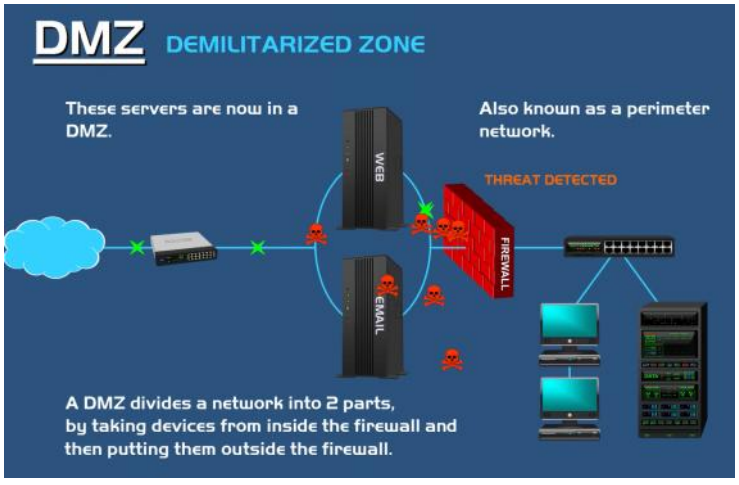
Public facing servers such as web servers and email servers are placed in the DMZ so external users can access them without reaching the internal network.

This prevents attackers from directly accessing sensitive internal systems even if a public server is compromised.



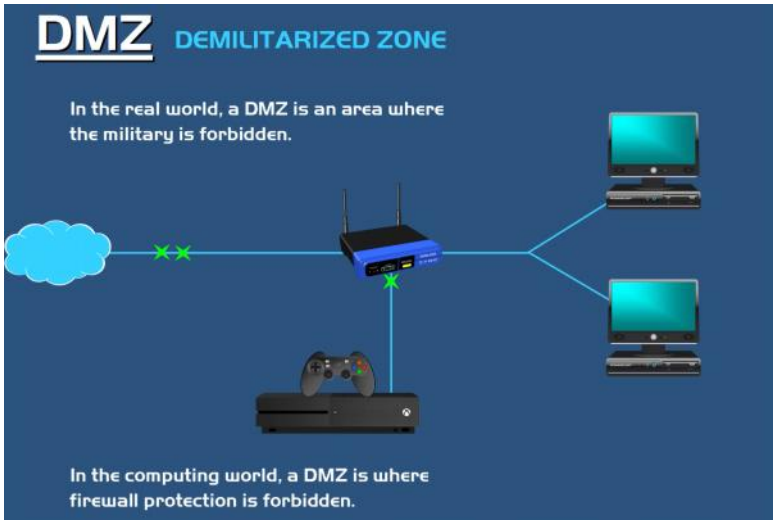






There are two common DMZ designs
Single firewall DMZ where one firewall separates the internet and internal network
Dual firewall DMZ where two firewalls are used which provides stronger security

In home routers a DMZ host means one device is fully exposed to the internet by forwarding all ports to it. This is often used for gaming devices but it is less secure.



DMZ
DEMILITARIZED ZONE
In the real world, a DMZ is an area where the military is forbidden.
In the computing world, a DMZ is where firewall protection is forbidden.
