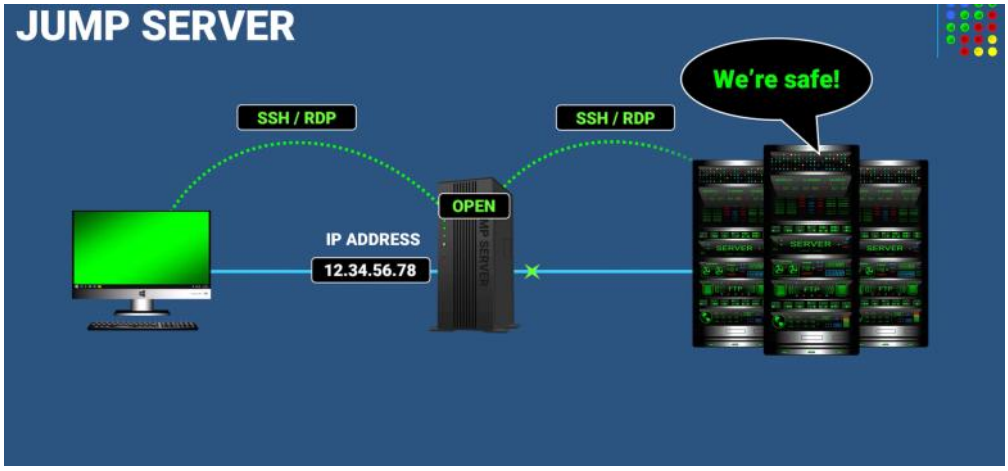
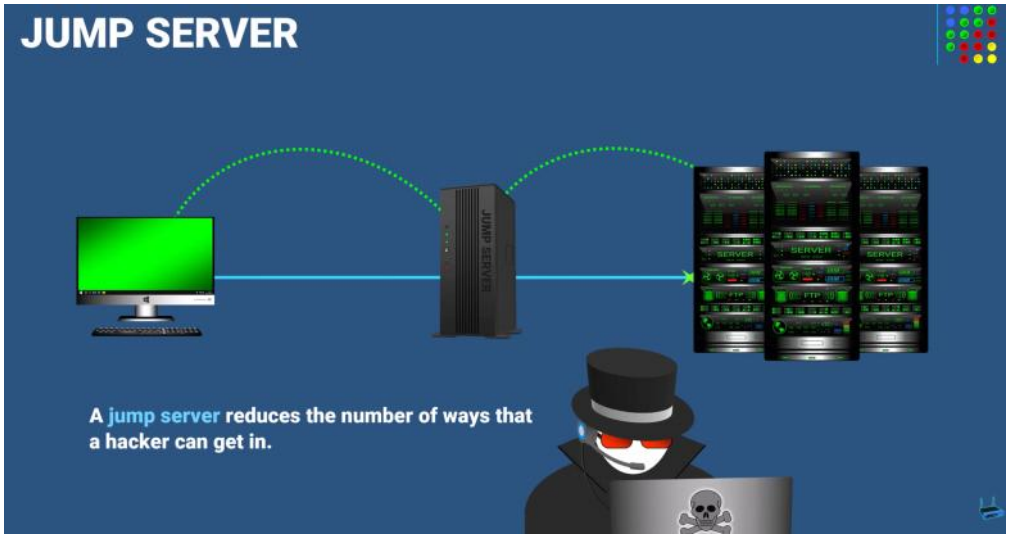
Jump Server

Wednesday, March 18, 2026 10:15 PM

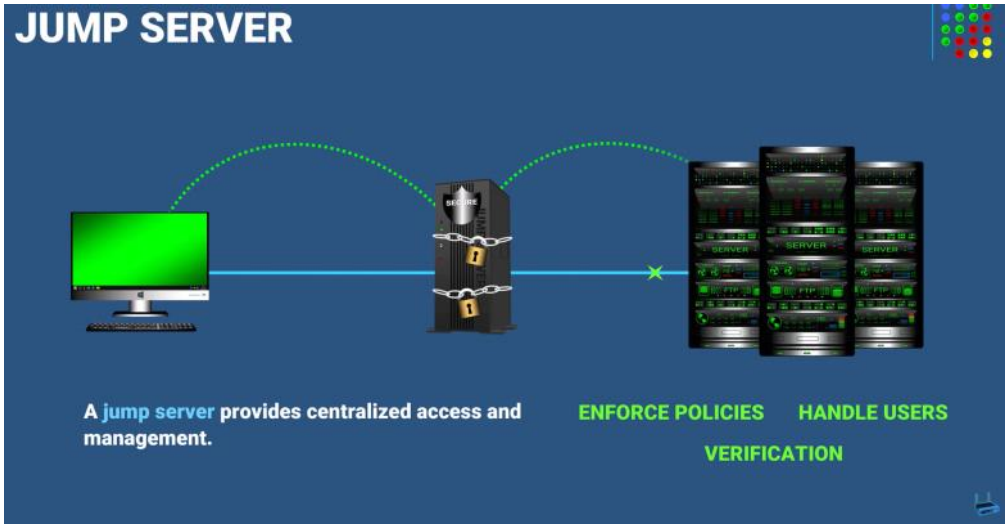
A jump server, also known as a bastion host, is a specialized server used to securely access and manage devices in a private network from an external location. Instead of exposing internal servers directly to the internet, users first connect to the jump server, which acts as a gateway or stepping stone.



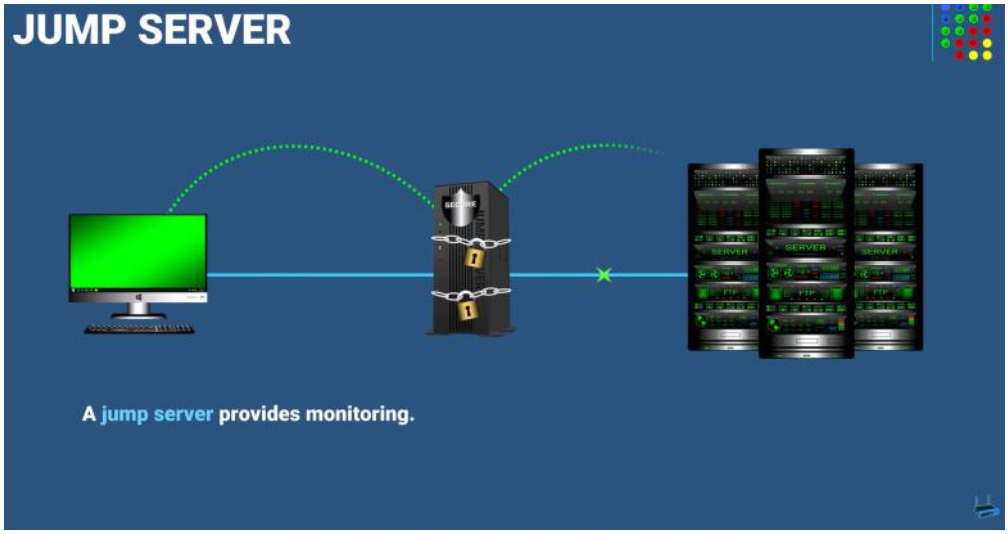
Key Benefits:



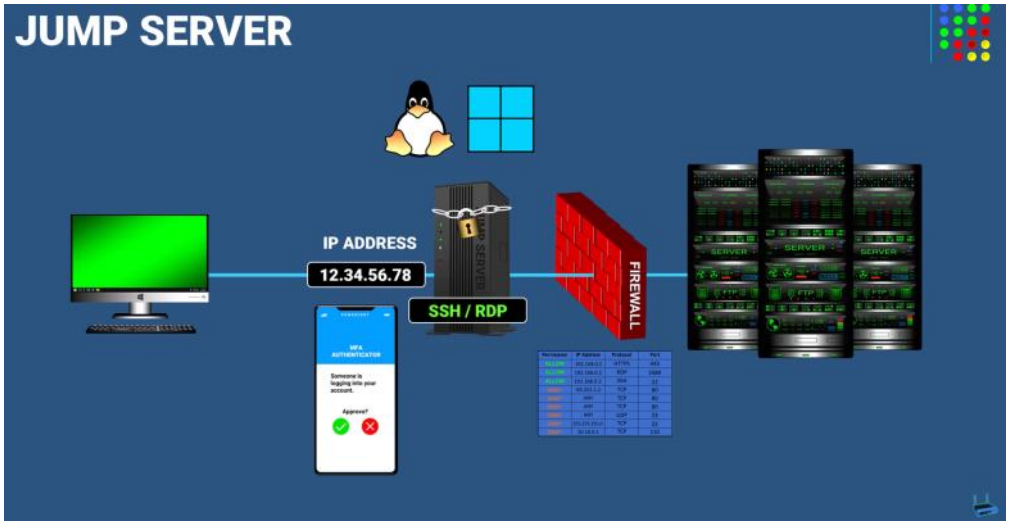
Enhanced Security: It reduces the attack surface by limiting internet access to a single, hardened device.



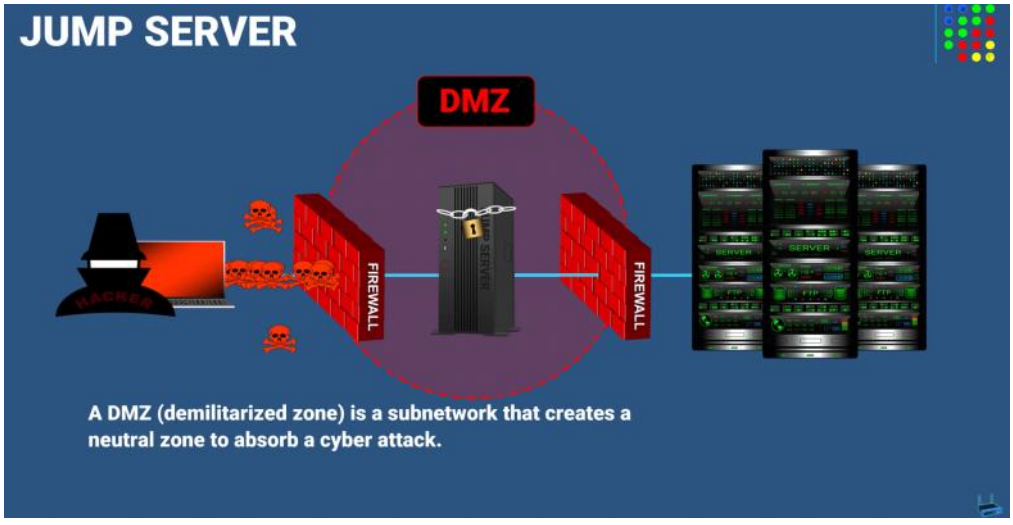
Centralized Access: It makes it easier to manage user rights, enforce security policies, and verify identities.



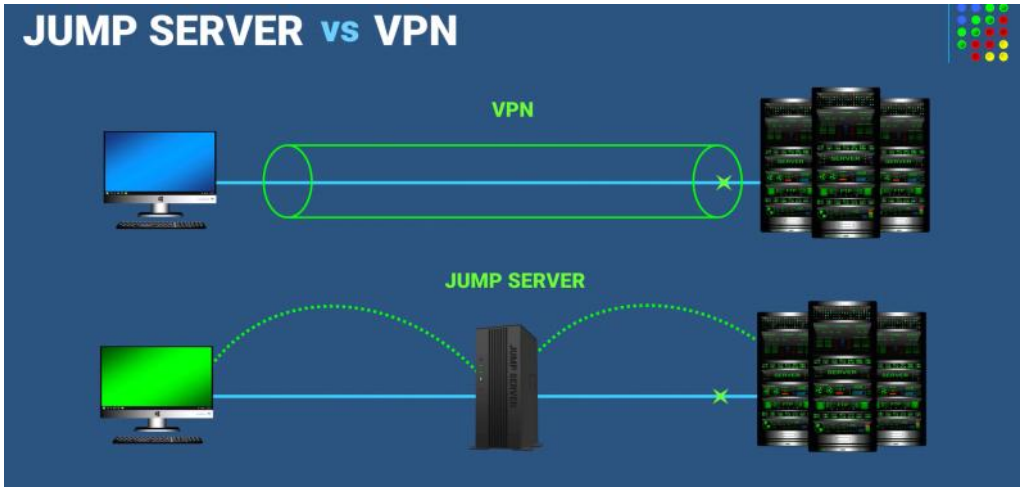
Monitoring: All user activity and traffic passing through the jump server can be logged and audited.



Jump servers can be physical or virtual machines and are typically configured with strict firewall rules and authentication measures like MFA (Multi-Factor Authentication).



Jump server can be extra protect by creating a DMZ to protect cyber attack



Jump Server
A jump server (bastion host) acts as a gateway or stepping stone to a private network. You must connect to the jump server first, and then to internal servers from there. It is primarily used for remote management of servers.

VPN
A VPN (Virtual Private Network) creates a direct, encrypted tunnel between your device and the target network. It is typically used for general work purposes, allowing remote employees to access resources as if they were in the same building.
