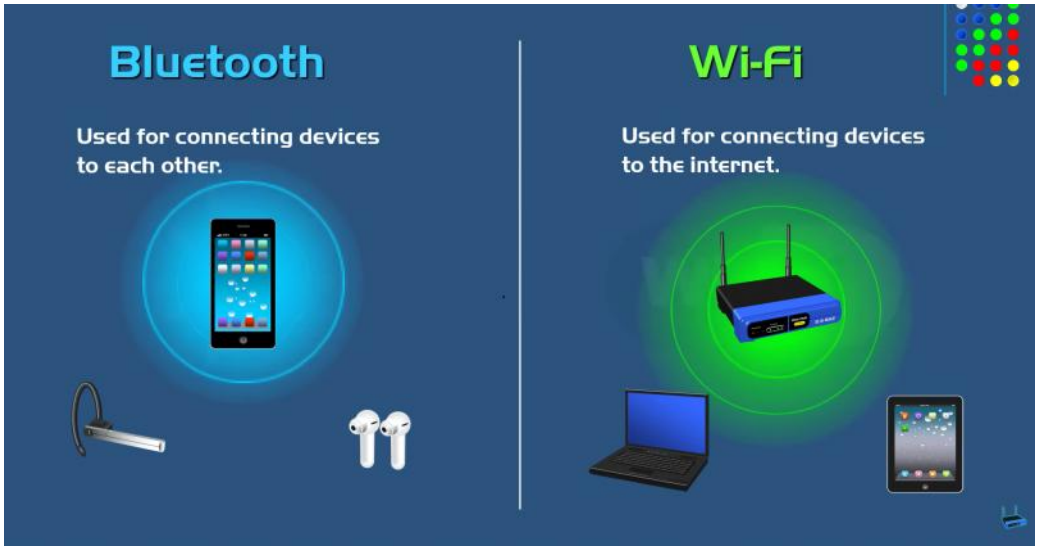
Bluetooth vs Wi-Fi

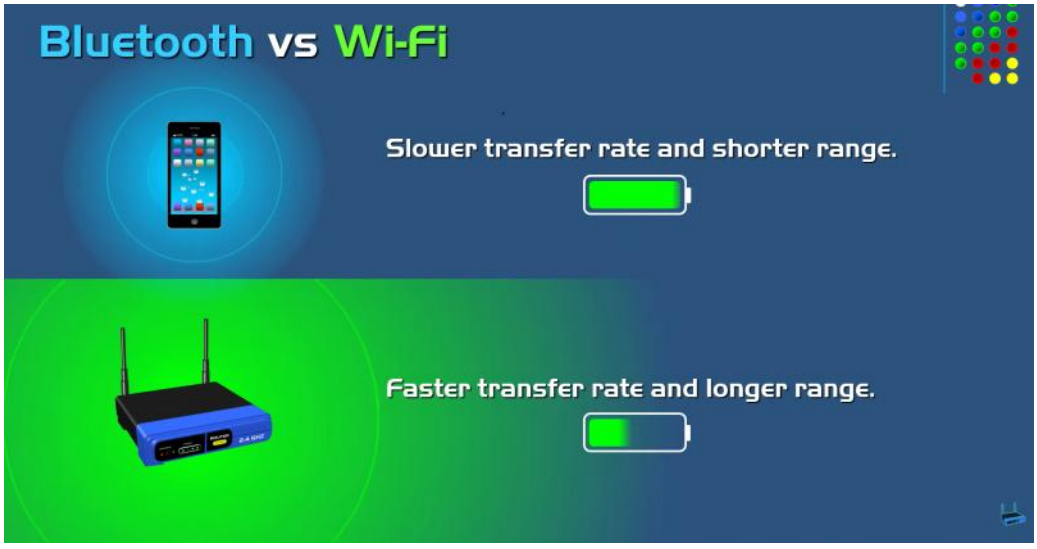
Saturday, April 4, 2026 11:54 AM

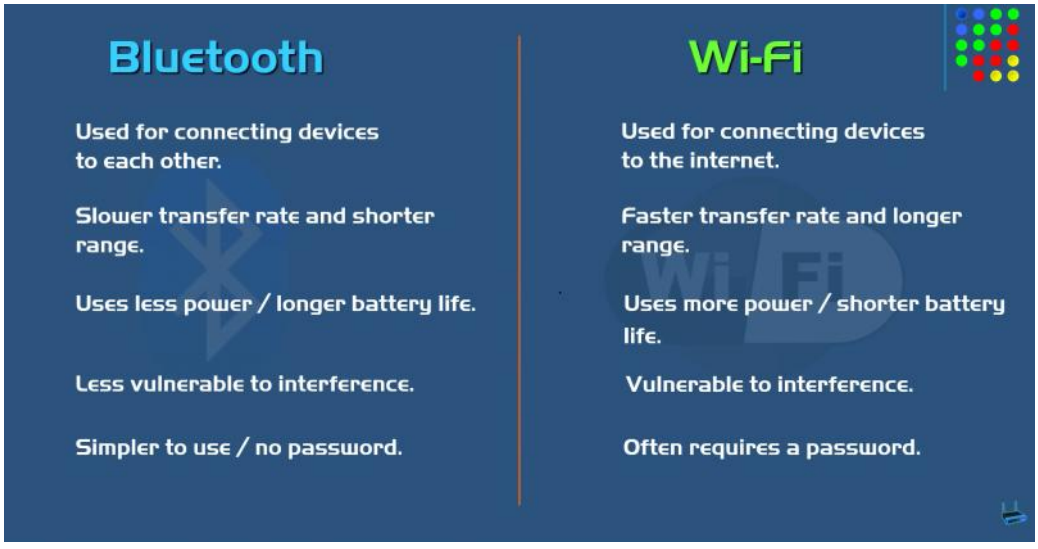
Bluetooth and Wi-Fi are both wireless technologies that use radio signals to connect devices, but they serve different purposes.

Bluetooth is mainly used to connect nearby devices directly, like earbuds, speakers, keyboards, or cars. It works over a short range, uses less power, and has slower data speed, which helps save battery. The devices have a computer chip inside them that can detect and emit the Bluetooth radio waves manly used to connect to each other and also it is called pairing. The range of Bluetooth is 10 meters.

Wi-Fi is used to connect devices to the internet through a router. It has a much longer range and faster speed compared to Bluetooth but consumes more power. It has a range of 30-91 meters.







In simple terms, Bluetooth is for device to device connection, while Wi-Fi is for internet access and larger networks.
