CDN - Content Delivery Network

Monday, April 27, 2026 7:22 PM

CDN Content Delivery Network helps websites load faster by delivering content from servers closer to the user instead of the main origin server.
A CDN works by establishing a point of presence (POP). A POP is made up of Edge servers which cache the content of the origin webserver.
It uses edge servers placed around the world to cache website data like HTML images and scripts. This reduces delay improves speed and lowers bandwidth cost. It also increases reliability by handling high traffic and prevents server crashes. Additionally CDN improves security by protecting against attacks like DDoS.
