DDNS

Thursday, March 12, 2026 11:24 PM

Dynamic DNS is a service that connects a changing (dynamic) IP address to a fixed hostname. Normally, DNS maps a domain name to a static IP address. But in home networks, internet providers usually give dynamic IP addresses that change over time.

If the IP address changes, accessing a device using the old IP will fail. DDNS solves this by automatically updating the new IP address and linking it to a custom hostname.

This allows users to access home devices like computers, routers, or security cameras remotely using a hostname instead of remembering the IP address. Even if the IP changes, the hostname will always point to the correct device.
